The Hadoop Stack, Part 3
Introduction to Spark

CSE 40822 – Cloud Computing – Spring 2016

Prof. Douglas Thain
University of Notre Dame

Three Case Studies

- Workflow: Pig Latin
  - A dataflow language and execution system that provides an SQL-like way of composing workflows of multiple Map-Reduce jobs.
- Storage: HBase
  - A NoSQl storage system that brings a higher degree of structure to the flat-file nature of HDFS.
- Execution: Spark
  - An in-memory data analysis system that can use Hadoop as a persistence layer, enabling algorithms that are not easily expressed in Map-Reduce.

Overview

- The Map-Reduce paradigm is fundamentally limited in expressiveness.
- Hadoop implementation of Map-Reduce is designed for out-of-core data, not in-memory data.
- Idea: Layer an in-memory system on top of Hadoop.
- Achieve fault-tolerance by re-execution instead of replication.

Map-Reduce Limitations

- As a general programming model:
  - It is perfect…. If your goal is to make a histogram from a large dataset!
  - Hard to compose and nest multiple operations.
  - No means of expressing iterative operations.
  - Not obvious how to perform operations with different cardinality.
    - Example: Try implementing All-Pairs efficiently.

- As implemented in Hadoop (GFS):
  - All datasets are read from disk, then stored back on to disk.
  - All data is (usually) triple-replicated for reliability.
  - Optimized for simple operations on a large amount of data.
  - Java is not a high performance programming language.

A Common Iterative Pattern in Data Mining

X = initial value
for(i=0; ; i++) {
    set S_{i+1} = apply F to set S_i
    value X = extract statistic from S_{i+1}
    if(X is good enough) break;
}

On Board: Implement in Map-Reduce
Can we do better?

The Working Set Idea

- Peter Denning, “The Working Set Model for Program Behavior”, Communications of the ACM, May 1968.
  - http://dl.acm.org/citation.cfm?id=363141
- Idea: conventional programs on one machine generally exhibit a high degree of locality, returning to the same data over and over again.
- The entire operating system, virtual memory system, compiler, and micro architecture are designed around this assumption!
- Exploiting this observation makes programs run 100X faster than simply using plain old main memory in the obvious way.

- (But in Map-Reduce, access to all data is equally slow.)

The Working Set Idea in Spark

- The user should identify which datasets they want to access.
- Load those datasets into memory, and use them multiple times.
- Keep newly created data in memory until explicitly told to store it.
- Master-Worker architecture: Master (driver) contains the main algorithmic logic, and the workers simply keep data in memory and apply functions to the distributed data.
- The master knows where data is located, so it can exploit locality.
- The driver is written in a functional programming language (Scala), so let's detour to see what that means.

Detour: Pure Functional Programming

- Functions are first class citizens:
  - The primary means of structuring a program.
  - A function need not have a name!
  - A function can be passed to another program as a value.
  - A pure function has no side effects.
- In a pure functional programming language like LISP
  - There are no variables, only values.
  - There are no side effects, only values.
- Hybrid languages that have functional capabilities, but do not prohibit non-functional idioms: Scala, F#, JavaScript…

By the way, Map-Reduce is Inspired by LISP:

map((lambda(x)(* x x)) (1 2 3 4))

reduce((lambda(x y) (+ x y)) (1 2 3 4))

Functions in Scala:

Define a function in the ordinary way:

def name (arguments) { code }

Construct an anonymous func as a value:

(arguments) => code

Accept an anonymous func as a parameter:

name: (arguments) => code

Example code:

```
def oncePerSecond(callback: () => Unit) {
        while( true ) { callback(); Thread sleep 1000 }
}

def main(args: Array[String]) {
        oncePerSecond(
                () =>println("time flies like an arrow...")
        )
}
```

A Scala Tutorial for Java Programmers: http://www.scala-lang.org/docu/files/ScalaTutorial.pdf

Parallel Operations in Scala

```
val n = 10;
for( i <- 1 to n ) {
    // run code each value of i in parallel
}
var items = List(1,2,3);
for ( i <- items ) {
    // run code for each value of i in parallel
}
```

Back to Spark, Using Scala

- A program to count all the error lines in a large text file:

```
val file = spark.textFile("hdfs://path/to/file");
val errs = file.filter(_.contains("ERROR"));
val ones = errs.map( _ => 1 );
val count = ones.reduce( _+_ );
```

_ means "the default thing that should go here."

```
val file = spark.textFile("hdfs://path/to/file");
val errs = file.filter( (x) => x.contains("ERROR"));
val ones = errs.map( (x) => 1 );
val count = ones.reduce( (x,y) => x+y );
```

On Board: Implement in Spark

Logistic Regression in Spark

```
val points = spark.textFile( … ).map(parsePoint).cache()

var w = Vector.random(D)

for( i <- 1 to ITERATIONS ) {
        val grad = spark.acculmulator( new Vector(D) )

        for( p <- points ) {
                val s = (1/(1+exp(-p.y*(w dot p.x)))-1)*p.y
                grad += s * p.x
        }
        w -= grad.value
}
```

Fault Tolerance via Recomputation

(Work out on the board.)

Result: Spark is 10-100X faster than Hadoop on equivalent iterative problems.

(It does everything in memory instead of disk.)
