Abstract—The performance of linear-programming decoding of a binary linear code described by a parity-check matrix depends on the set of pseudo-codewords associated to this matrix and in particular, on the set of minimal pseudo-codewords.

This paper attempts to provide an algebraic characterization of the minimal pseudo-codewords. It also provides a connection between the fundamental cone of a Tanner graph and the fundamental cone of its Forney-style factor graph.

Index Terms—Fundamental cone, linear-programming decoding, low-density parity-check code, pseudo-codewords.

I. INTRODUCTION

Linear-programming (LP) decoding has emerged as an interesting approach to decoding binary linear codes [1], [2]. The present paper attempts to present a characterization of the set of pseudo-codewords and, in particular, of the set of minimal pseudo-codewords, the objects which determine the performance of an LP decoder.

The main focus of the present paper is the derivation of certain results on the structure of minimal pseudo-codewords. Such results are immediately relevant to LP decoding. Additionally, through the intuitive connection made by Koetter and Vontobel [3], [4] between message-passing iterative (MPI) decoding and LP decoding, these results have implications for MPI decoding as well. In addition, these results have relevance also to compressed sensing through the connection made in [5], [6] between channel coding LP decoding and compressed sensing LP decoding.

In [7], the authors introduce two classes of pseudo-codewords, called absdet-pseudo-codewords and perm-pseudo-codewords, which seem to be important in the characterization of the performance of LP decoding and MPI decoding. In this paper we develop further on their characterization of the performance of LP decoding and pseudo-codewords, which seem to be important in the absdet-pseudo-codewords and perm-pseudo-codewords.

Section II we list basic notations and definitions. In Section III we give a bound on the support of all minimal pseudo-codewords. Based on this bound, in Section IV we build further on the importance of the absdet-pseudo-codewords and give a complete characterization of the minimal pseudo-codewords of the nullspace type. In Section V we attempt a characterization of the remaining minimal pseudo-codewords.

II. BASIC NOTATIONS AND DEFINITIONS

Let \( \mathbb{Z} \), \( \mathbb{R} \), and \( \mathbb{F}_2 \) be the ring of integers, the field of real numbers, and the finite field of size 2, respectively. If \( M \) is some matrix and if \( R \) and \( S \) are subsets of the row and column index sets, respectively, then \( M_{R,S} \) is the submatrix of \( M \) that contains only the rows of \( M \) whose index appears in the set \( R \) and only the columns of \( M \) whose index appears in the set \( S \); if \( R \) equals the set of all row indices of \( M \), we will write \( M_R \) instead of \( M_{R,S} \); and we will use \( S \setminus i \) for \( S \setminus \{i\} \).

Let \( H = (h_{j,i}) \in \mathbb{F}_2^{n \times n} \) be a parity-check matrix of some binary linear code. We define the sets \( J(H) \) and \( Z(H) \) to be the set of row and column indices of \( H \), and \( I_j(H) \triangleq \{i \in I \mid h_{j,i} = 1\} \).

We review the following important definitions.

The fundamental cone \( K(H) \) of \( H \) is the set of all vectors \( \omega \in \mathbb{R}^n \) that satisfy

\[
\omega_i \geq 0 \quad \text{for all } i \in I(H), \quad (1)
\]

\[
\omega_i \leq \sum_{i' \in I_j(H)} \omega_{i'} \quad \text{for all } j \in J(H), \quad \text{for all } i \in I_j(H). \quad (2)
\]

A vector \( \omega \in K(H) \) is called a pseudo-codeword. If such a vector lies on an edge of \( K(H) \), it is called a minimal pseudo-codeword. Moreover, if \( \omega \in K(H) \cap \mathbb{Z}^n \) and \( \omega \pmod{2} \in C \),

\footnote{In particular, in all the cases where an exact characterization of the min-
sum algorithm is possible, block-wise graph-cover decoding gives also the
correct predictions, and in all the cases where an exact characterization of the
sum-product algorithm is possible, symbol-wise graph-cover decoding gives also the
correct predictions.}

* Supported by NSF Grants DMS-0708033 and TF-0830608.
then $\omega$ is called an unscaled pseudo-codeword. (For a motivation of these definitions, see [3]).

As mentioned in [3], minimal pseudo-codewords in $K(H)$ completely characterize the region in the log-likelihood ratio vector space where LP decoding decides for the all-zero codeword; the knowledge of non-minimal pseudo-codewords is however also valuable since such pseudo-codewords can be used to bound this decision region.

In [7], the notions of det-vectors, absdet-pseudo-codewords, and perm-pseudo-codewords were introduced. We briefly review these definitions.

Let $C$ be a binary linear code described by a parity-check matrix $H \in \mathbb{F}_2^{m \times n}$, $m < n$. Any size-$(m+1)$ subset $S$ of $I(H)$ defines a det-vector based on $S$ to be the vector $\nu \in \mathbb{Z}^n$ with components

$$\nu_i \triangleq \begin{cases} \det(H_{S \setminus i}) & \text{if } i \in S \\ 0 & \text{otherwise} \end{cases},$$

where $\eta_S(i) \in \{0,1,\ldots, |S|-1\}$ is the index of $i$ within the set $S$ and $\det_S(\cdot)$ is the $\mathbb{Z}$-determinant operator. The absdet-vector based on $S$ is the vector $\omega \in \mathbb{Z}^n$ with components

$$\omega_i \triangleq \begin{cases} |\det(H_{S \setminus i})| & \text{if } i \in S \\ 0 & \text{otherwise} \end{cases},$$

i.e., the components of the absdet-vectors are the absolute value of the components of the det-vector. Finally, the perm-vector based on $S$ is the vector $\omega \in \mathbb{Z}^n$ with components

$$\omega_i \triangleq \begin{cases} \text{perm}_Z(H_{S \setminus i}) & \text{if } i \in S \\ 0 & \text{otherwise} \end{cases},$$

where $\text{perm}_Z(\cdot)$ denotes the $\mathbb{Z}$-permanent operator.

We remind the following lemma from [7].

**Lemma 1** Let $C$ be a binary linear code described by the parity-check matrix $H \in \mathbb{F}_2^{m \times n}$, and let $\nu \in \mathbb{R}^n$ be a vector that satisfies $H \cdot \nu^T = 0^T$ in $\mathbb{R}$. Then the vector $\omega \in \mathbb{R}^n$ with components $\omega_i \triangleq |\nu_i|$, $i \in I$, satisfies $\omega \in K(H)$.

For convenience, we will extend the absolute value notation from complex numbers to vectors and write $\omega = |\nu|$ for a vector satisfying the conditions of Lemma 1 and say that such an $\omega$ is a pseudo-codeword of the nullspace type. Since the det-vector $\nu$ based on $S$ satisfies $H \cdot \nu^T = 0^T$ in $\mathbb{Z}$ we obtain that the absdet-vector $\omega$ based on $S$ is an unscaled pseudocodeword of $H$ of the nullspace type. In [7], it was shown that the perm-vectors are also unscaled pseudo-codewords. We will see that they are not necessarily of the nullspace type.

### III. Bound on the Size of the Support of a Minimal Pseudo-Codeword

The following theorem gives an upper bound on the size of the support of any minimal pseudo-codeword. This bound will be used in identifying all the minimal pseudo-codewords of the nullspace type. $^2$

$^2$Results equivalent to the ones in this section were also derived in [8] using a different approach.

**Theorem 2** If $C$ is a binary linear code described by a parity-check matrix $H \in \mathbb{F}_2^{m \times n}$, $m \leq n$, and $\omega$ is a minimal pseudo-codeword for $H$, then

$$|\text{supp}(\omega)| \leq m + 1. \tag{3}$$

If $\omega$ is a minimal pseudo-codeword of the nullspace type, then

$$|\text{supp}(\omega)| \leq \text{rank}_K(H) + 1 \leq m + 1. \tag{4}$$

**Proof:** Let $A$ be the $k \times n$ matrix of rank $n-1$, $k \geq n-1$, obtained from the inequalities (1) and (2) that are satisfied with equality. Then $A \cdot \omega^T = 0^T$ in $\mathbb{R}$.

Let $|\text{supp}(\omega)| = l$. For convenience and without loss of generality, we suppose that the first $l$ positions of $\omega$ are nonzero; otherwise, we use column operations on $A$ to bring the columns corresponding to the support of $\omega$ to the first $l$ positions. Appropriately interchanging rows, we can rearrange the matrix $A$ to have the form $A = \begin{bmatrix} M & N \\ 0 & I_{n-l} \end{bmatrix}$. In addition, we can assume that each row of $H$ is represented in $M$ at most once by an inequality as in (2). Indeed, if one row would have two associated rows in $M$, then we would have a submatrix of $M$ of the form

$$\begin{bmatrix} -1 & 1 & 1 & 1 & \ldots & 0 & 0 & \ldots \\ 1 & -1 & 1 & 1 & \ldots & 0 & 0 & \ldots \end{bmatrix},$$

which has kernel non-negative vectors with a zero component on the positions of the support of $\omega$, an impossible situation; and if the submatrix is

$$\begin{bmatrix} -1 & 1 & 0 & 0 & \ldots \\ 1 & -1 & 0 & 0 & \ldots \end{bmatrix}$$

then the second row does not contribute to the rank of $A$ and it can be discarded.

 Appropriately subtracting multiples of some of the last $n-l$ rows from some of the rows corresponding to the matrix $N$, we can reduce the matrix to

$$A = \begin{bmatrix} M & 0 \\ 0 & I_{n-l} \end{bmatrix}. \tag{5}$$

The rank of $A$ can then be easily computed as

$$n - 1 = \text{rank}_K(A) = n - l + \text{rank}_K(M), \tag{6}$$

from which $\text{rank}_K(M) = l - 1 = |\text{supp}(\omega)| - 1$ and since $\text{rank}_K(M) \leq m + 1$ we obtain $|\text{supp}(\omega)| \leq m + 1$.

If $\omega$ is of the nullspace type, then let $\nu \in \mathbb{R}^n$ such that $\omega = |\nu|$ and $H \cdot \nu^T = 0^T$ in $\mathbb{R}$. Changing the sign of the $i$th column of $H$ if $\nu_i < 0$, we obtain a submatrix $M'$ of $A$ corresponding to inequalities (2), which can be further reduced as above to give $M$. Since $\text{rank}(M) \leq \text{rank}(M') = \text{rank}(H)$ we obtain the claim. $\blacksquare$

**Remark 3** From the above proof we see that we can assume that $A$ has the representation given by (5) after a permutation of the components of $\omega$ so that the nonzero components are on the first $l = |\text{supp}(\omega)|$ positions. In addition, we can take the matrix $M$ above to have full rank, equal to $l - 1$ according to (6). Therefore a matrix $M$ of minimal size can be obtained from an $(l - 1) \times l$ submatrix of $H$ with columns indexed by the support $\text{supp}(\omega) \triangleq \{i_1, \ldots, i_l\}$ of $\omega$, such that on each of the rows one of the entries is changed from 1 into $-1$, giving $M \cdot (\omega_{i_1}, \ldots, \omega_{i_l})^T = 0^T$ in $\mathbb{R}$. We state this fact in the following lemma. $\blacksquare$
Lemma 4 Let $C$ be a binary linear code described by a parity-check matrix $H \in \mathbb{F}_2^{m \times n}$ and let $\omega$ be a minimal pseudo-codeword for $H$ with $\text{supp}(\omega) = \{i_1, \ldots, i_l\}$.

Then there exists a full rank $(l-1) \times l$ submatrix of $H$ with columns indexed by the support of $\omega$ for which it is possible to change on each of its rows one of the entries of $1$ into $-1$ to obtain a full rank $(l-1) \times l$ matrix $M$ such that $M \cdot (\omega_{i_1}, \ldots, \omega_{i_l})^T = 0^T$ (in $\mathbb{R}$).

Moreover, if $A$ denotes the matrix of rank $n-1$ associated to the inequalities of the fundamental cone that are satisfied by any $\omega$,

Then there exists a full rank $(l-1) \times l$ submatrix of $H$ with columns indexed by the support of $\omega$ for which it is possible to change on each of its rows one of the entries of $1$ into $-1$ to obtain a full rank $(l-1) \times l$ matrix $M$ such that $M \cdot (\omega_{i_1}, \ldots, \omega_{i_l})^T = 0^T$ (in $\mathbb{R}$).

Moreover, if $A$ denotes the matrix of rank $n-1$ associated to the inequalities of the fundamental cone that are satisfied by any $\omega$,

This means that any pseudo-codeword $\omega$ can be transformed into a minimal pseudo-codeword by changing the entries of $1$ to $-1$.

IV. MINIMAL PSEUDO-CODEWORDS OF THE NULLSPACE TYPE

The pseudo-codewords of the null-space type are of interest because of the recent connections that were established between channel coding and compressed sensing.

A relevant question in this connection is when a nonzero vector in the null-space of a measurement matrix is mapped, through the absolute value mapping of Lemma 1, to a minimal pseudo-codeword. This section provides the answer.

Suppose $H$ has full rank $m$ over $\mathbb{R}$ and suppose for convenience, without loss of generality, that the first $m$ columns are linearly independent. The following theorem shows a simple fact about the set of det-vectors $\{\nu_j\} \in \mathbb{R}^{m \times n}$ based on the size $m + 1$ set $S_j \triangleq \{0, 1, \ldots, m-1\}$. Namely, it shows that this set of $n-m$ vectors forms a basis over $\mathbb{Z}$ for the set of all solutions of the system $H \cdot \nu^T = 0^T$ over $\mathbb{Z}$. Applying (8) now Lemma 1, we obtain that the absdet-pseudo-codewords “span” the subset of pseudo-codewords of the nullspace type. This means that any pseudo-codeword $\omega$ obtained from a vector $\nu \in \mathbb{Z}^n$ in the nullspace of $H$, i.e., $H \cdot \nu^T = 0^T$ over $\mathbb{Z}$, by the absolute value mapping, i.e., $\omega = |\nu|$, has the property that there exist $a_i \in \mathbb{Z}$, $m \leq i \leq n-1$, such that $\omega = \sum_{i=m}^{n-1} a_i \nu_i$. In addition, after proper scaling, the set of vectors $\{\nu_j \mod 2\}_{m \leq i \leq n-1}$ forms a basis for the set of codewords in $C$, giving a generator matrix.

We state this result in a more general form.

Theorem 5 Let $C$ be a binary linear code described by the parity-check matrix $H \in \mathbb{F}_2^{m \times n}$, $(m < n)$ of rank $m' \leq m$ over $\mathbb{R}$, and let $H'$ be an $m' \times n$ submatrix of $H$ of full rank. Let $S = \{i_1, i_2, \ldots, i_{m'}\} \subset \text{supp}(H')$ be a set of $m'$ $\mathbb{Z}$-linearly independent columns of $H'$. For each $i \in \{\nu_i \mod 2\}_{m \leq i \leq n-1}$ forms a basis for the set of codewords in $C$, giving a generator matrix.

The two codewords form another generator matrix.

Proof: The set of solutions of $H \cdot \nu^T = 0^T$ is a subspace of $\mathbb{R}^n$ of dimension $n - m'$. Note that the set of det-vectors $\{\nu_j\} \in \mathbb{R}^{m \times n}$ based on the size $m + 1$ set $S_j \triangleq \{0, 1, \ldots, m-1\}$. Namely, it shows that this set of $n-m$ vectors forms a basis over $\mathbb{Z}$ for the set of all solutions of the system $H \cdot \nu^T = 0^T$ over $\mathbb{Z}$. Applying (8) now Lemma 1, we obtain that the absdet-pseudo-codewords “span” the subset of pseudo-codewords of the nullspace type. This means that any pseudo-codeword $\omega$ obtained from a vector $\nu \in \mathbb{Z}^n$ in the nullspace of $H$, i.e., $H \cdot \nu^T = 0^T$ over $\mathbb{Z}$, by the absolute value mapping, i.e., $\omega = |\nu|$, has the property that there exist $a_i \in \mathbb{Z}$, $m \leq i \leq n-1$, such that $\omega = \sum_{i=m}^{n-1} a_i \nu_i$. In addition, after proper scaling, the set of vectors $\{\nu_j \mod 2\}_{m \leq i \leq n-1}$ forms a basis for the set of codewords in $C$, giving a generator matrix.

We state this result in a more general form.

Theorem 6 Let $C$ be a binary linear code described by the parity-check matrix $H \in \mathbb{F}_2^{m \times n}$, $(m < n)$ of rank $m' \leq m$ over $\mathbb{R}$, and let $H'$ be an $m' \times n$ submatrix of $H$ of full rank. Let $S = \{i_1, i_2, \ldots, i_{m'}\} \subset \text{supp}(H')$ be a set of $m'$ $\mathbb{Z}$-linearly independent columns of $H'$. For each $i \in \{\nu_i \mod 2\}_{m \leq i \leq n-1}$ forms a basis for the set of codewords in $C$, giving a generator matrix.
Proof: From Lemma 2 we have \( l \leq \text{rank}_a(H) + 1 \). Let \( \nu \in \mathbb{R}^n \) such that \( \omega = [\nu] \) and \( H \cdot \nu^T = 0^T \) in \( \mathbb{R} \). Then \( H_S \cdot \nu_S^T = 0^T \) and \( \omega_S = [\nu_S] \), so \( \omega_S \) is a pseudo-codeword for \( H_S \) of the nullspace type. We also have that the matrix \( M \) in the representation of Lemma 4 must correspond to a submatrix of \( H_S \) of rank \( l - 1 \). Therefore, \( \omega_S \) is a minimal pseudo-codeword for \( H_S \) and necessarily \( \text{rank}(H_S) = l - 1 \). Let \( T \subset \mathcal{F}(H) \) be a set of \( l - 1 \) \( \mathbb{Z} \)-linearly independent rows of \( H_S \), let \( \mu_S \in \mathbb{Z}^l \) denote the det-vector of \( H_{T,S} \) based on \( S \) and let \( \mu \in \mathbb{Z}^n \) be its length-\( n \) extension obtained by adding zero components on the positions \( i \notin S \). According to Theorem 5, \( \mu_S \) gives a basis over the integers for the set of solutions of \( H_S \cdot \nu_S^T = 0^T \) in \( \mathbb{Z} \). Then there exists \( a \in \mathbb{Z} \), such that \( \nu_S = a \mu_S \). It implies that, up to scaling by \( a \), the two vectors are equal resulting in \( \omega = a \mu \). Since \( \mu \) is an absdet-pseudo-codeword for \( H_{T,I_H(H)} \), the claim follows.

The following theorem gives a family of matrices for which the absdet-pseudo-codewords are always minimal.

**Theorem 8** Let \( C \) be a binary linear code described by a parity-check matrix \( H \in \mathbb{F}_2^{m \times n} \), \( m < n \). Let \( S \) be a size-\((n+1)\) subset of \( I(H) \), let \( m' \triangleq \text{rank}_a(H_S) \), and let \( H' \in H_S \) be an \( m' \times (m' + 1) \) matrix of full rank. Let \( \omega \in \mathbb{Z}^{m' + 1} \) be the absdet-pseudo-codeword of \( H' \) based on \( I(H') \) and define \( \omega \in \mathbb{Z}^n \) to be its natural \( n \)-extension

\[
\omega_i \triangleq \begin{cases} 
\omega_i & \text{if } i \in I(H') \\
0 & \text{otherwise}
\end{cases}
\]

Suppose that \( H' \) has row degree at most 3, then \( \omega \) is a minimal pseudo-codeword for \( H \).

**Proof:** Let \( \nu = (\nu_i) \in \mathbb{Z}^{m' + 1} \) such that \( H' \cdot \nu^T = 0^T \) in \( \mathbb{Z} \) and \( \omega = [\nu] \). Let \( M' \) be the \( m' \times (m' + 1) \) matrix such that

\[
\text{col}_i(M') \triangleq \begin{cases} 
-\text{col}_i(H') & \text{if } \nu_i < 0 \\
\text{col}_i(H') & \text{if } \nu_i \geq 0
\end{cases}
\]

where \( \text{col}_i(M') \) and \( \text{col}_i(H') \) denote the \( i \)-th column of \( M' \) and \( H' \), respectively. Then \( M' \cdot \omega^T = 0^T \) in \( \mathbb{Z} \). Since the row degree of \( H' \) is at most 3, each equation in \( H' \cdot \nu^T = 0^T \) involves at most 3 variables. Therefore, changes of signs must occur in the nonzero columns \( \nu_i \) that participate in that equation: if the equation involves three nonzero components then two must have the same sign and one not; if there are only two nonzero components involved in the equation, then they must be equal in their absolute value and of different sign. Therefore each row of \( M' \) must be nonzero (since \( m' \) is full rank) and must contain either only one negative entry or only one positive entry. Therefore, \( M' \) is a submatrix of the matrix \( A \) describing the inequalities of the fundamental cone that are satisfied with equality. Since \( \text{rank}_a(H') = \text{rank}_a(M') = m' \), we obtain, together with \( n = (m' + 1) \) equations \( \omega_i = 0 \) for all \( i \notin I(H') \), that \( \omega \) is minimal for \( H \).

**V. MINIMAL PSEUDO-CODEWORDS NOT OF THE NULLSPACE TYPE**

The minimal pseudo-codewords that are not of the nullspace type are unfortunately not (yet) as compactly described. What we can say so far about the behavior of these pseudo-codewords is the following.

Let \( \omega \) be a minimal pseudo-codeword not in the \( \mathbb{R} \)-nullspace of \( H \), of support size \( l \) with \( l \leq m + 1 \) (for \( m < n \)). Then, there does not exist a vector \( \nu \) in the \( \mathbb{R} \)-nullspace of \( H \) such that \( [\nu] = \omega \), but there could be two or more \( \nu_1, \nu_2, \ldots, \nu_k \) such that \( [\nu_i] = \omega \) and each \( \nu_i \) is in the nullspace of some \( |R_i| \times n \) submatrix \( H_i \), \( |R_i| < m, i = 1, 2, \ldots, k \). We give an example.

**Example 9** Let \( H \triangleq \begin{pmatrix} 1 & 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \end{pmatrix} \)

and \( \omega = (1, 1, 3, 2, 1, 1, 1) \). Let \( \nu_1 \triangleq (1, 1, -3, 2, -1, -1, -1), \nu_2 \triangleq (1, 1, -3, 2, 1, 1, 1), \nu_3 \triangleq (1, 1, 3, -2, -1, -1, 1), \nu_4 \triangleq (1, 1, -3, -2, 1, -1, 1) \).

They all map in absolute value to \( \omega \), so \( [\nu_i] \). We have

\[
H \cdot \nu_1^T = (-2, 0, 0, -2, 4, 0)^T, \quad H \cdot \nu_2^T = (0, 0, 4, 0, 4, 2)^T, \\
H \cdot \nu_3^T = (4, 0, -2, 0, 0, 0)^T, \quad H \cdot \nu_4^T = (0, 6, 0, -4, 0, 0)^T,
\]

so \( \omega = [\nu_i] \) is a pseudo-codeword of the nullspace type for \( H_{(1,2,5)}, H_{(0,1,3)}, H_{(1,3,4,5)}, H_{(1,2,4,5)}, H_{(1,3,4,5)} \), and \( H_{(0,2,4,5)} \), respectively. Note that \( \omega \) is a minimal pseudo-codeword for \( H \).

We note that the union of the rows of \( H \) that are considered for \( \nu_3 \) and \( \nu_4 \) is \( \mathcal{F}(H) \), so we can describe \( \omega \) using only these two vectors. We conjecture that all minimal pseudo-codewords that are not of the nullspace type can be described similarly with only two vectors. Unfortunately, there is not more we can say about these pseudo-codewords at this time.

**VI. THE ASSOCIATED FACTOR GRAPH PERSPECTIVE**

In this last section we ask if new information on pseudo-codewords can be obtained by taking a factor graph perspective. Of particular interest is the behavior of the absdet- and perm-pseudo-codewords under the map between a Tanner graph \( G \) and a to the Forney-style factor graph of \( G \).

To be more explicit, to an LDPC code \( C \) described by an \( m \times n \) parity-check matrix \( H \) to which a Tanner graph \( G \) with \( m \) check nodes and \( n \) variables nodes corresponds, we can associate a Forney-style factor graph (FFG): the variable nodes are associated with the edges of the Tanner graph and the Tanner graph’s variable nodes become each a repetition code. There is also the variant where a half-edge is added to every repetition code, however the topology of the resulting factor graphs is the same.
To this new factor graph, we can also associate a matrix $H'$ and a code $C'$ whose parity-check code is $H'$. In general, the number of rows of $H'$ is equal to $m + \sum_{i=0}^{n-1}(\deg(x_i) - 1)$, where $\deg(x_i)$ equals the degree of the node $x_i$ in the Tanner graph. The number of columns of $H'$ is equal to the number of edges of the Tanner graph: $\sum_{i=0}^{n-1}(\deg(x_i) - 1)$.

Moreover, if the Tanner graph has, e.g., variable nodes $x_0, x_1, x_2, \ldots, x_{n-1}$, of degrees $3, 2, 4, \ldots$, then there exists a bijective mapping between pseudo-codewords in one and the other.

A natural question when analyzing pseudo-codewords for the FFG is if there are one-to-one mappings of absdet-pseudo-codewords and perm-pseudo-codewords from $H$ to $H'$?

The answer is no and yes. The following example will provide some intuition.

**Example 10** Let

$$H = \begin{bmatrix} 1 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 \end{bmatrix}.$$ 

The absdet- and perm-pseudo-codewords are: $(1,1,0,1)$ and $(3,1,2,1)$. We have a node $x_0$ of degree 1, $x_1$ of degree 3 and $x_2$ and $x_3$ of degree 2. The following matrices represent two possible incidence matrices of the Tanner graph defined by the FFG:

$$H' = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \quad H'' = \begin{bmatrix} 1 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$ 

The absdet-pseudo-codeword $(1,1,1,0,0,1)$ and perm-pseudo-codeword $(3,1,1,2,2,1,1)$ of $H'$ map indeed onto $(1,1,0,1)$ and $(3,1,2,1)$, respectively. Matrix $H''$ has absdet-pseudo-codeword $(1,1,1,1,2,2,1,1)$ and perm-pseudo-codeword $(3,1,1,1,1,2,2,1,1)$. These map onto $(1,1,2,1)$ and $(3,1,2,1)$, respectively. Note that $(1,1,2,1)$ is a new minimal pseudo-codeword for the Tanner graph of $H$. In this case, we obtain new information through this FFG mapping.

We can show that the pseudo-codewords of $H$ obtained by projecting the perm-pseudo-codewords of $H'$ will be equal to the perm-pseudo-codewords of $H$. Here is an intuitive explanation: the entries are permanents of square submatrices $M$ and $M'$ of $H$ and $H'$, respectively, which are sums of all elementary products. There is a one-to-one correspondence between the elementary products in $M$ and the ones in $M'$. We omit the proof of this due to space constraint.

This is not the case for the absdet-pseudo-codewords, as Example 10 already suggested. The reason for this is that in computing the determinant entries of the absdet-pseudo-codewords we take the elementary products together with the signature sign, which can result in new pseudo-codewords through the projection.

**Theorem 11** Let $C$ and $C'$ be the binary linear codes described by the $m \times n$ parity-check matrix $H$, and by the matrix $H'$ associated to the FFG of $H$, respectively. Let $f : K(H') \to K(H)$ be a natural bijective projection map on the set of pseudo-codewords of the two matrices. If $\text{Perm}(H)$ and $\text{Perna}(H')$ are the sets of the perm-pseudo-codewords for $H$ and $H'$, respectively, then $f(\text{Perm}(H')) = \text{Perm}(H)$.

**VII. Conclusions**

In this paper we have provided a complete characterization of minimal pseudo-codewords of the nullspace type using the set of absdet-pseudo-codewords. An important question for future research concerns the impact of these analytical results on the understanding of the overall performance of the LP decoder. Results in this direction can be found in [8] which explores ideas for fast LP decoding of LDPC codes. Results equivalent to the ones in Section III, which were independently derived there using a different approach, prove to be useful towards this goal. In addition, this paper provides bridging tools for the connections with compressed sensing [5], [6].

**VIII. Acknowledgements**

We would like to thank Pascal O. Vontobel for his valuable comments and for the many fruitful discussions related to the topic, and to the reviewers for their very helpful suggestions.
