Received June 10, 2009

Three new layered uranyl phosphates, Ba₃(UO₂)₂(HPO₄)₂(PO₄)₃, Ba(UO₂)F(PO₄)₂, and Cs₂(UO₂)₂(PO₄)₃, were synthesized under mild hydrothermal conditions. These compounds serve as models for uranium alteration phases that might form when spent nuclear fuel is subjected to oxidizing groundwater containing dissolved phosphate. In order to address the possibility of the incorporation of the key fission product ¹²⁹I in the form of iodate into uranyl alteration phases, the substitution of IO₃⁻ for the structurally related PO₄(ΟH)²⁻ or PO₄³⁻ unit was probed. Iodate incorporation into these phases was investigated using LA-ICP-MS, and these data indicate incorporation of iodine with levels as high as 4162 ppm.

Introduction

A deep understanding of the crystal chemistry of uranium compounds and minerals is motivated in part by their potential impact upon the mobility of radionuclides in a geological repository for nuclear waste and in vadose zones contaminated with actinides. In addition to these important environmental aspects of uranium chemistry, these materials are of substantial fundamental interest because of the rich coordination environments of U(VI) that includes tetragonal, pentagonal, and hexagonal bipyramids. These uranyl polyhedra can link together with each other through different connecting modes such as corner- or edge-sharing. Many oxoanions, such as sulfate, selenate, phosphate, iodate, silicate, and molybdate, have been used as ligands for uranyl cations and result in the formation of various structures containing one-dimensional chains, two-dimensional sheets, or three-dimensional frameworks. These uranium-containing compounds also have several interesting and potentially useful physical and chemical properties, including catalysis, luminescence, and ion-exchange.

Uranium phosphates have been the subject of special interest for a variety of reasons, one of which is their application in the separation of uranium from other components in spent nuclear fuel because of the relatively low solubility of these compounds. 12 Uranyl phosphates are abundant and structurally rich in natural systems, 13 and their formation subsequently affects the migration (or mobility) of uranium in aqueous systems. Therefore, it is important to study the structure, bonding, stability, and spectroscopic properties of uranium phosphates.

Recently, we discovered the unprecedented intercalation of HIO$_3$ into the layered hydrated uranyl iodate, UO$_2$(IO$_3$)$_2$·2H$_2$O, to yield UO$_2$(IO$_3$)$_2$(H$_2$O)·2HIO$_3$. 6d This intercalation reaction provides a mechanism by which iodine, in the form of iodate, might be taken up by layered uranyl compounds. 129I is one of the key radionuclides of concern that has been released into the environment as the result of nuclear weapons testing and nuclear power operations, especially at locations like the Hanford Site, Savannah River, Nevada Testing Grounds, and Oak Ridge, and is expected to be one of the primary radionuclides of concern in the proposed repository at Yucca Mountain. 14 129I is a long-lived ($t_{1/2} = 1.7 \times 10^7 \text{ b}$) β-emitter.

In an effort to predict the mechanism for the retardation of the release 7bSe from spent nuclear fuel, Chen, Burns, and Ewing analyzed a number of uranyl alteration phases and proposed in which phases anion substitution might take place. 15 The speciation of selenium in water bears some similarities with that of iodine in that the trigonal pyramidal selenite, SeO$_3^{2-}$, anion exists under oxidizing conditions (along with SeO$_4^{2-}$), and SeO$_3^{2-}$ has the same basic structure as that of iodate, albeit with a different charge. The principle mechanisms proposed were that the (SeO$_3$)$_2$ units could substitute for (CO$_3$)$_2$ in phases such as sklodowskite, Mg[(UO$_2$)(SiO$_3$OH)$_2$]$_2$(H$_2$O)$_6$, for (PO$_4$) units in the uranyl phosphates phurcalite Ca$_2$[(UO$_2$)$_3$(PO$_4$)$_2$O$_2$](H$_2$O)$_7$, as well as the potential for substitution of (SeO$_3$)$_2$ for (CO$_3$)$_2$ in rutherfordine, UO$_2$(CO$_3$). Very recently a report was issued by some of the authors of this present study demonstrating the incorporation of iodine in the form of iodate and metaperiodate into the uranyl silicate, uranophane. 16 In addition, there has been at least one study that indirectly indicates that (SeO$_3$)$_2$ can substitute for (CO$_3$)$_2$ in rutherfordine UO$_2$(CO$_3$). 17 In consideration of the structural similarities between iodate and hydrogen phosphate, PO$_4$(OH)$^{2-}$, we launched a study on the incorporation of iodate into uranyl phosphate phases.

Herein, we report the preparation, structures, and spectroscopic characterization of three new uranyl phosphate compounds, Ba$_3$(UO$_2$)$_2$(HPO$_4$)$_2$(PO$_4$)$_2$, Ba(UO$_2$)F(PO$_4$)$_2$, and Cs$_2$(UO$_2$)$_2$(PO$_4$)$_2$. We also probe the incorporation of iodate into these uranyl phosphate phases using laser-ablation inductively coupled plasma mass spectroscopy (LA-ICP-MS).

### Experimental Section

**Syntheses.** UO$_2$(NO$_3$)$_2$·6H$_2$O (98%, Alfa-Aesar), H$_3$PO$_4$ (85%, Alfa-Aesar), HF (40%, Alfa-Aesar), H$_3$BO$_3$ (99.99%, Alfa-Aesar), K$_2$CO$_3$ (99%, Sigma-Aldrich), Cs$_2$CO$_3$ (99.9%, Alfa-Aesar), BaCO$_3$ (99.8%, Alfa-Aesar), and HIO$_3$ (99.5%, Alfa-Aesar) were used as received without further purification. Distilled and Millipore filtered water with resistance of 18.2 MΩ·cm was used in all reactions. PTFe-lined autoclaves were used for all reactions. SEM/EDX analyses were performed using a JEOL JSM-700F. **Caution:** While the UO$_2$·(NO$_3$)$_2$·6H$_2$O used in this study contained depleted U, standard precautions for handling radioactive materials should be followed. Older sources of uranyl nitrate may not be depleted and enhanced care is warranted for these samples. The HF is extremely hazardous and appropriate skin protection and ventilation is needed.

Ba$_3$(UO$_2$)$_2$(HPO$_4$)$_2$(PO$_4$)$_2$ (BaUP). BaUP was synthesized by loading BaCO$_3$ (204.2 mg, 1.035 mmol), UO$_2$·(NO$_3$)$_2$·6H$_2$O (173.1 mg, 0.345 mmol), H$_3$BO$_3$ (21.4 mg, 0.345 mmol), H$_3$PO$_4$ (0.05 mL, 1.035 mmol), and 0.5 mL of water in a 23 mL PTFe-lined autoclave. The autoclave was sealed and heated at 190 °C in a box furnace. After 4 days, the furnace was cooled to room temperature at a rate of 9 °C/h. The product was washed with water and methanol. Yellow-green crystals were left to dry in the air. Yield: 207.4 mg (90.3% based on U). EDX analysis provided a Ba:U:P ratio of 3:2:4.

Ba(UO$_2$)$_2$F(PO$_4$)$_2$ (BaUPF). BaUPF was synthesized by loading BaCO$_3$ (204.2 mg, 1.035 mmol), UO$_2$·(NO$_3$)$_2$·6H$_2$O (173.1 mg, 0.345 mmol), H$_3$BO$_3$ (21.3 mg, 0.345 mmol), H$_3$PO$_4$ (0.05 mL, 1.035 mmol), HF (0.1 mL, 2.32 mmol), and 0.5 mL of water in a 23 mL PTFe-lined autoclave. The autoclave was sealed and heated at 190 °C in a box furnace. After 5 days, the furnace was cooled to room temperature at a rate of 9 °C/h. The product was washed with water and methanol. Yellow-green crystals were left to dry in the air. Yield: 149.4 mg (83.1% based on U). EDX analysis provided a Ba:U:P ratio of 3:2:4.

Cs$_2$(UO$_2$)$_2$(PO$_4$)$_2$ (CsUP). CsUP was synthesized by loading Cs$_2$CO$_3$ (266.3 mg, 0.817 mmol), UO$_2$(NO$_3$)$_2$·6H$_2$O (136.8 mg, 0.273 mmol), H$_3$BO$_3$ (16.8 mg, 0.272 mmol), H$_3$PO$_4$ (0.05 mL, 1.035 mmol), and 0.5 mL of water in a 23 mL PTFe-lined autoclave. The autoclave was sealed and heated at 190 °C in a box furnace. After 5 days, the furnace was cooled to room temperature at a rate of 9 °C/h. The product was washed with water.

and methanol and allowed to dry. The reaction product contained yellow-green crystals of the title compound as the major product. Yield: 74.4 mg (54.8% based on U). EDX analysis provided a Cs:U:P ratio of 1:1:1.

Crystallographic Studies. Single crystals of Ba₃(UO₂)₂(HPO₄)₂(PO₄)₂, Ba(UO₂)₂F(PO₄), and Cs₂(UO₂)₂(PO₄)₂ with dimensions of 0.076 mm × 0.066 mm × 0.021 mm, 0.061 mm × 0.038 mm × 0.036 mm, and 0.088 mm × 0.028 mm × 0.020 mm, respectively, were selected and mounted on glass fibers with epoxy and aligned on a Bruker SMART APEX CCD X-ray diffractometer with a digital camera. Intensity measurements were performed using graphite monochromated Mo Kα radiation from a sealed tube with a monocapillary collimator. The intensities and positions of reflections of a sphere were collected by a combination of 3 sets of exposure frames. Each set had a different φ angle for the crystal, and each exposure covered a range of 0.3° in ω. A total of 1800 frames were collected with an exposure time per frame of 10 s for Cs₂(UO₂)₂(PO₄)₂, 30 s for Ba₃(UO₂)₂(HPO₄)₂(PO₄)₂, and 40 s for Ba(UO₂)₂F(PO₄). Determination of integrated intensities and global cell refinement were performed with the Bruker SAINT (version 6.02) software package using a narrow-frame integration algorithm. A semiempirical absorption correction was applied using SADABS. The program suite SHELXTL (version 5.1) was used for space group determination (XPREP), direct methods structure solution (XS), and least-squares refinement (XL). The final refinements included anisotropic displacement parameters for all atoms and a secondary extinction parameter. Some crystallographic details are listed in Table 1.

Powder X-ray Diffraction. Powder X-ray diffraction patterns were collected with a Rigaku Miniflex powder X-ray diffractometer using Cu Kα (λ = 1.54056 Å) radiation. The collected patterns were compared with those calculated from single crystal data using ATOMS. Incorporation of Iodate into Uranyl Phosphates. In order to compare iodate uptake results from crystals grown in the presence of iodate versus those that are added back into iodate solutions, two different experiments were designed as follows: (1) BaUP, BaUPF, and CsUP were synthesized in the presence of HIO₃ and labeled as BaUP1, BaUPF1, and CsUP1. (2) A total of 0.1136, 0.0461, and 0.0905 g of pure BaUP, BaUPF, and CsUP crystals, respectively, were reacted with iodic acid solutions under mild hydrothermal condition (190 °C, 5 days), and labeled as BaUP2, BaUPF2, and CsUP2. The stoichiometric ratios of uranium to iodate in all reactions were kept as 10:1. The prepared crystals were washed several times with hot water and ethanol prior to analysis.

(20) ATOMS; version 6.1; Shape Software: Kingsport, TN, 2004.
in an attempt to remove any iodate that might be sorbed on the surfaces of the crystals. These single crystals were then ablated using a New Wave Research UP-213 Nd: YAG laser under a He carrier gas at \(\sim 0.710 \text{ L/min}\) and an Ar sample gas flow of \(\sim 0.9 \text{ L/min}\). The contents of iodine in these crystals were determined by a high-resolution magnetic sector Thermo Finnigan Element 2 inductively coupled plasma mass spectrometer (ICP-MS).

**Results and Discussion**

**Crystal Structure of \(\text{Ba}_3(\text{UO}_2)_2(\text{HPO}_4)_2(\text{PO}_4)_2\)**. The title compound contains one crystallographically unique U(VI) center that is strongly bonded to two oxygen atoms, forming a nearly linear \(\text{UO}_2^{2+}\) cation. The \(\text{U} = \text{O}\) bond lengths within the uranyl cation are 1.774(5) Å \((\times 2)\) and the \(\text{O} - \text{U} - \text{O}\) angle is 176.5(2)°. The \(\text{UO}_2^{2+}\) cation is further coordinated equatorially by five oxygen atoms and forms a \(\text{UO}_7\) pentagonal bipyramid. Within these \(\text{UO}_7\) polyhedra, the equatorial \(\text{U} - \text{O}\) bond distances range from 2.278(5) to 2.436(4) Å. There are also two crystallographically unique phosphorus atoms observed in the structure, and both of them are coordinated by four oxygen atoms in a tetrahedral geometry. The \(\text{P}(1)\text{O}_4^{3-}\) tetrahedron consists of four bridging oxygen atoms bound to three uranyl polyhedra. The \(\text{P} - \text{O}\) bond distances within \(\text{P}(1)\text{O}_4^{3-}\) range from 1.524(5) to 1.539(5) Å. Although \(\text{P}(2)\) has a similar tetrahedral coordination environment with oxygen atoms, it acts as a terminal ligand and connects to only one uranyl polyhedron. Within the tetrahedron, one oxygen atom is protonated with a \(\text{P} - \text{O}(6)\) bond distance of 1.598(5) Å. The bond distances of the remaining three \(\text{P} - \text{O}\) bonds range from 1.495(5) to 1.543(5) Å. Two crystallographically unique \(\text{Ba}\) atoms are found in the structure, and both of them have 10-coordinate environments. The \(\text{Ba} - \text{O}\) bond distances range widely from 2.642(5) to 3.178(5) Å. The calculated BVS values\(^{(1)}\) for \(\text{U}(1), \text{P}(1), \text{P}(2), \text{Ba}(1),\) and \(\text{Ba}(2)\) are 6.01, 4.97, 5.11, 2.11, and 2.05, respectively. Selected bond distances are listed in Table 2.

The structure of \(\text{Ba}_3(\text{UO}_2)_2(\text{HPO}_4)_2(\text{PO}_4)_2\) is of particular interest because it has a new uranyl layered topology. As shown in Figure 1, each uranyl polyhedron is coordinated by three bridging \(\text{P}(1)\text{O}_4^{3-}\) tetrahedra and one terminal \(\text{HP}(2)\text{O}_4^{2-}\) tetrahedron. Among these three bridging \(\text{P}(1)\text{O}_4^{3-}\) tetrahedra, one of them is connected to the uranyl polyhedron through edge-sharing and the other two combine to the uranyl polyhedron through corner-sharing. These uranyl polyhedra are joined together through bridging \(\text{P}(1)\text{O}_4^{3-}\) ligands to form a \([\text{UO}_2\text{F}(\text{PO}_4)_2]^{6-}\) layer in the \([abc]\) plane with terminal \(\text{HP}(2)\text{O}_4^{2-}\) ligands pointing out of the layer. These anionic layers further stack along the \(a\) axis and form a layered structure. \(\text{Ba}^{2+}\) cations, which act as counterions, reside in the interlayer space between adjacent \([\text{UO}_2\text{F}(\text{PO}_4)_2]^{6-}\) layers. A view of the two-dimensional \([\text{UO}_2\text{F}(\text{PO}_4)_2]^{6-}\) layer in \(\text{Ba}_3(\text{UO}_2)_2(\text{HPO}_4)_2(\text{PO}_4)_2\) that extends in the \([abc]\) plane is shown in Figure 2. An illustration of the stacking of the \([\text{UO}_2\text{F}(\text{PO}_4)_2]^{6-}\) layer

---

---

**Figure 3.** Illustration of the stacking of the \([\text{UO}_2\text{F}(\text{PO}_4)_2]^{6-}\) layers in \(\text{Ba}_3(\text{UO}_2)_2(\text{HPO}_4)_2(\text{PO}_4)_2\) along the \(a\) axis. Uranyl and phosphate are shown as green and yellow polyhedra, respectively. Blue balls stand for barium cations.

**Figure 4.** View of the two-dimensional \([\text{UO}_2\text{F}(\text{PO}_4)_2]^{6-}\) layer in \(\text{Ba}_3(\text{UO}_2)_2(\text{HPO}_4)_2(\text{PO}_4)_2\) that extends in the \([abc]\) plane. Uranyl and phosphate are shown as green and yellow polyhedra, respectively. Blue and light blue balls stand for barium and fluorine atoms, respectively.
in Ba₂(UO₂)₂(HPO₄)₂(PO₄)₂ along the a axis is shown in Figure 3.

Crystal Structure of Ba(UO₂)₂F(PO₄)₂. In the structure of Ba(UO₂)₂F(PO₄)₂, there is only one crystallographically unique U(VI) center that exits as a nearly linear UO₂⁺ cation with U=O bond lengths of 1.774(5) and 1.780(5) Å, and an O−U−O angle of 175.1(3)°. The uranyl cation is further coordinated by three oxygen atoms and two fluorine atoms in the equatorial plane to form a UO₅F₂ pentagonal bipyramid. The equatorial U−O bond lengths range from 2.317(5) to 2.398(5) Å, and the U−F bond lengths are 2.376(5) and 2.395(5) Å. One distinct phosphorus site and one distinct barium site are observed in the structure. The phosphorus atom is coordinated by four oxygen atoms in a tetrahedral geometry. The P−O bond distance ranges from 1.509(6) to 1.545(6) Å. Nine-coordinate Ba⁺ ions are found interacting with eight oxygen atoms and one fluorine atom. Ba−O bond lengths range from 2.644(6) to 3.183(6) Å, and the Ba−F bond length is 2.791(5) Å. The calculated BVS values for U(1), P(1), and Ba(1) are 6.07, 5.08, and 2.12, respectively. Selected bond distances are listed in Table 3.

The uranyl pentagonal bipyramids are joined together along the c axis to form a chain extending along the b axis. These chains are further linked by tridentate phosphate anions to form a [(UO₂)₂F(PO₄)₂]⁻⁻ layer in the [ab] plane. The anionic layer has a similar topology to the [(UO₂)₂F₄(HPO₄)₂]⁻ sheet in the structure of [(CH₃)₂NH(CH₂)₂NH(CH₃)][(UO₂)₂F₄(HPO₄)₂]. These anionic layers stack along the c axis with barium cations imbedded in the interlayer space as counterions. A view of the two-dimensional [(UO₂)₂F(PO₄)₂]⁻⁻ layer in Ba(UO₂)₂F(PO₄)₂ that extends in the [bc] plane is shown in Figure 4. An illustration of the stacking of the [(UO₂)₂F(PO₄)₂]⁻⁻ layers in Ba(UO₂)₂F(PO₄)₂ along the c axis is shown in Figure 5.

Crystal Structure of Cs₂(UO₂)₂(PO₄)₂. There are two crystallographically unique U(VI) centers in the structure of Cs₂(UO₂)₂(PO₄)₂. The U=O bond lengths are 1.777(9) and 1.781(1) Å in the U(1)O₂⁺ cation and 1.785(9) Å and 1.791(1) Å in the U(2)O₂⁺ cation. The O−U−O angles are 176.4(4)° and 177.0(4)°, respectively. Both of the UO₂⁺ cations are further equatorially coordinated by five oxygen atoms to form UO₇ pentagonal bipyramids in which the equatorial U−O bond lengths range from 2.249(8) to 2.601(8) Å for U(1) and 2.227(8) to 2.584(8) Å for U(2). There are also two crystallographically unique phosphorus atoms observed in the structure of Cs₂(UO₂)₂(PO₄)₂, and both of them are coordinated by four oxygen atoms to form a tetrahedral geometry. The P−O bond distances range from 1.489(9) Å. The remaining three P−O bond distances within P(1)O₄³⁻ range from 1.547(8) to 1.580(9) Å. Furthermore, the P(1)O₄³⁻ tetrahedron is connected to two uranyl polyhedra via edge-sharing and to another two uranyl polyhedra via corner-sharing. While the P(2)O₄³⁻ tetrahedron consists of four bridging oxygen atoms bound to four uranyl polyhedra, and the P−O bond distances range from 1.530(8) to 1.549(9) Å. Two different Cs⁺ cations are observed in Cs₂(UO₂)₂(PO₄)₂, and both of them are coordinated by 10 oxygen atoms. The Cs(1)−O and Cs(2)−O bond distances range from 2.584(8) to 2.601(8) Å for (UO₂)F(PO₄)₂ along the c axis. Uranyl and phosphate are shown as green and yellow polyhedra, respectively.

(22) Ok, K. M.; Doran, M. B.; O’Hare, D. *Dalton Trans.* 2007, 3325.
from 2.932(8) to 3.60(1) Å, and 2.930(8) to 3.635(8) Å, respectively. The calculated BVS values\(^{21}\) for U(1), U(2),\(^3\) P(1), P(2), Cs(1), and Cs(2) are 5.96, 5.95, 4.92, 4.95, 0.98, and 1.13, respectively. Selected bond distances are listed in Table 4.

The structure of Cs\(_2\)(UO\(_2\))\(_2\)(PO\(_4\))\(_2\) also has a new and highly unusual uranyl layered topology. As shown in Figure 6, each of the U(1) or U(2) uranyl polyhedra connects to another two U(1) or U(2) uranyl polyhedra through corner-sharing to form a chain of uranyl polyhedra along the b axis. Each U(1) uranyl polyhedra chain also connects to another U(2) uranyl polyhedra chain via corner-sharing along the c axis. Between the adjacent U(1) and U(2) polyhedra, there is a P(1)O\(_4^{3−}\) tetrahedron. Both of the U(1) and U(2) polyhedra share an edge with the P(1)O\(_4^{3−}\) tetrahedron. The terminal P−O bond in the P(1)O\(_4^{3−}\) tetrahedron alternately point up and down. The ribbons of uranyl polyhedra are joined together by tetradenate P(2)O\(_4^{3−}\) through corner-sharing to form a [(UO\(_2\))\(_2\)(PO\(_4\))\(_2\)]\(^{2−}\) layer in the [bc] plane. Cesium cations reside in the interlayer space between two adjacent [(UO\(_2\))\(_2\)(PO\(_4\))\(_2\)]\(^{2−}\) layers. A view of the two-dimensional [(UO\(_2\))\(_2\)(PO\(_4\))\(_2\)]\(^{2−}\) layer in Cs\(_2\)(UO\(_2\))\(_2\)(PO\(_4\))\(_2\) that extends in the [bc] plane is shown in Figure 6. An illustration of the stacking of the [(UO\(_2\))\(_2\)(PO\(_4\))\(_2\)]\(^{2−}\) layers in Cs\(_2\)(UO\(_2\))\(_2\)(PO\(_4\))\(_2\) along the a axis is shown in Figure 7.

**Incorporation of Iodate into Layered Uranyl Phosphates.** Iodate-incorporated BaUP, BaUPF, and CsUP single crystals were analyzed using laser-ablation ICP-MS in which single crystals were first ablated by a laser and subsequently analyzed by ICP-MS at a mass of 127. As shown in Figure 8, there is a low and smooth background for the \(^{127}\)I mass before the laser-ablation starts. As soon as the laser shutter opens (start at 60 s), stable peaks of \(^{127}\)I were observed that demonstrate the existence of iodine in the single crystals of BaUP, BaUPF, and CsUP. Table 5 shows the concentration of incorporated iodate in all samples. The average content of iodine in BaUP1, BaUPF1, and CsUP1 are 4162, 2923, and 100 ppm, respectively. It is clear that the iodate uptake values change significantly between these compounds with the highest uptake occurring for the most open layers.

**Figure 7.** Illustration of the stacking of the [(UO\(_2\))\(_2\)(PO\(_4\))\(_2\)]\(^{2−}\) layers in Cs\(_2\)(UO\(_2\))\(_2\)(PO\(_4\))\(_2\) along the b axis. Uranyl and phosphate are shown as green and yellow polyhedra, respectively. Blue balls stand for Cs atoms.

![Figure 8](image)

**Figure 8.** LA-ICP-MS spectrum for \(^{127}\)I and \(^{238}\)U in a typical iodate incorporated Cs\(_2\)(UO\(_2\))\(_2\)(PO\(_4\))\(_2\) single crystal.

The most likely mechanism for iodate incorporation into these compounds is the substitution of iodate for phosphate, (IO\(_3^{−}\)) ↔ (PO\(_4^{3−}\)). Thus, the different coordination of PO\(_4^{3−}\) in the structures will result in a different quantity of incorporated iodine. As discussed previously, BaUP has two different PO\(_4^{3−}\) sites: P(1)O\(_4^{3−}\) is connected to three UO\(_7\) pentagonal bipyramids and P(2)O\(_4^{3−}\) is connected to one UO\(_7\) pentagonal bipyramid. It is unlikely that the substitution IO\(_3^{−}\) ↔ P(1)O\(_4^{3−}\) will happen because this will disrupt the structural connectivity. However, P(2)O\(_4^{3−}\) is connected to only one UO\(_7\) bipyramid by corner-sharing, which makes it possible for IO\(_3^{−}\) to substitute for PO\(_4^{3−}\). IO\(_3^{−}\) ↔ P(2)O\(_4^{3−}\). With the incorporation of iodate into the structure, an additional charge-balancing mechanism is required to maintain electrostatic neutrality. The most likely possibility is losing some Ba\(^{2+}\) cations between the sheets, which can be described as follows:

\[
\text{Ba}_3(\text{UO}_2)_2(\text{HPO}_4)_2(\text{PO}_4)_2 + x\text{IO}_3^{−} \rightarrow \\
\text{Ba}_{(3−0.5x)}(\text{UO}_2)_2(\text{HPO}_4)_{(2−x)}(\text{IO}_3)_x(\text{PO}_4)_2 + \\
0.5xBa^{2+} + x\text{HPO}_4^{2−}
\]

(1)

The PO\(_4^{3−}\) tetrahedron in BaUPF is connected to three UO\(_7\)F\(_2\) pentagonal bipyramids, with O···O contacts in the range of 2.473–2.536 Å. This is similar to the O···O contacts of IO\(_3^{−}\) in several uranyl iodates whose O···O distances range from 2.484 Å to 2.793 Å.\(^{6a,d}\) Because of the small O···O contacts differences between PO\(_4^{3−}\) and IO\(_3^{−}\), it is probable for IO\(_3^{−}\) to substitute for PO\(_4^{3−}\) via sharing three oxygen atoms with the UO\(_7\)F\(_2\) pentagonal bipyramids, if structural connectivity is not disrupted.
by the elimination of an anion apex due to the substitution.

$$\text{Ba(UO}_2\text{)}\text{F(PO}_4\text{)} + x\text{IO}_3^- \rightarrow \text{Ba}_{(1-x)}\text{(UO}_2\text{)}\text{F(PO}_4\text{)}(1-x)\text{(IO}_3\text{)}_x + x\text{Ba}^{2+} + x\text{PO}_4^{3-}$$

(2)

There is a $\text{P(2)O}_4^{3-}$ tetrahedron in $\text{CsUP}$ that is connected to four $\text{UO}_2^-$ pentagonal bipyramids by corner-sharing. Because of the potential structure disruption, it is unlikely for iodate to substitute for $\text{P(2)O}_4^{3-}$. However, the $\text{P(1)O}_4^{3-}$ tetrahedron is connected to two uranyl polyhedra via edge-sharing and to another two uranyl polyhedra via corner-sharing, which makes it possible for $\text{P(1)O}_4^{3-}$ to be substituted by $\text{IO}_3^-$. Thus, the mechanism of iodate substitute for $\text{PO}_4^{3-}$ in $\text{CsUP}$ should be similar to that in $\text{BaUPF}$.

$$\text{Cs}_2(\text{UO}_2)_2(\text{P(1)O}_4)(\text{P(2)O}_4) + x\text{IO}_3^- \rightarrow \text{Cs}_{2(1-x)}(\text{UO}_2)_2(\text{P(1)O}_4)(1-x)(\text{IO}_3)_x(\text{P(2)O}_4) + 2x\text{Cs}^+ + x\text{P(1)O}_4^{3-}$$

(3)

By extrapolating from LA-ICP-MS data, substitutions of phosphate become more facile with fewer shared corners or edges in the structure. Thus, the iodate concentration in $\text{BaUP1}$ is higher than $\text{BaUPF1}$. The iodate incorporation abilities before crystal growth and after are different according to different compounds. $\text{BaUP1}$ and $\text{BaUPF1}$, which are grown together with iodate, can uptake much more iodate than $\text{BaUP2}$ and $\text{BaUPF2}$. However, there is no significant difference between $\text{CsUP1}$ and $\text{CsUP2}$.

**Conclusions**

The question posed in the title of this manuscript has been answered in the affirmative. Iodate can indeed be incorporated at significant levels into the structures of uranyl phosphates that form under mild hydrothermal conditions. This indicates that iodate also can be incorporated into some natural uranyl phosphate minerals such as phurcalite, $\text{Ca}_2[(\text{UO}_2)_3(\text{PO}_4)_2\text{O}_2](\text{H}_2\text{O})_7$. Therefore, the mobility of $\text{I}^{129}$ in geologic repositories can be reduced significantly through this mechanism.
