- 1). According to an old story, a brave Dutchman saved his (or perhaps her) country by plugging a hole in the dike with a finger. In this problem we examine just how difficult this feat was.
- a. Consider the dike depicted below. Assuming that the hole is 20ft below sea level and the density of sea water is 1.04 g/cm^3 , calculate the force required to plug a hole 1 inch in diameter.

b. repeat the calculation for a hole 1 foot in diameter. This is why it is a good idea to catch leaks early!

- 2). Compute the viscosity of oxygen, nitrogen, CO₂, and air at room temperature (20°C) and 1 atm pressure, and compare it to values you find in a reference of your choice (the web is helpful here). The Chapman-Enskog equation described in chapter 1 of BS&L is useful here!
- 3). The viscosity of many liquids is approximately exponential in the inverse of the temperature in °K (e.g., the equation in chapter 1 of BS&L).
- a. Using this, and data from the Dow Chemical website:

http://www.dow.com/glycerine/resources/physicalprop.htm

determine constants for such a model near room temperature (plot the correlation and the data up). Use the data from 10° C to 40° C.

- b. By what factor does the viscosity change if the temperature increases from 20°C to 21°C?
- c. The viscosity over the entire range of temperature from 0° C to 100° C is well fit by a quadratic function of 1/T. If we include this extra term, what is the new answer to part b?

- 4). Pool drains can be dangerous things there was a tragic case a few years ago in this area where a child was stuck in a drain on the bottom, plugging it, and drowning as a result. Here we look at a somewhat simpler problem. Suppose a ball of radius R is plugging a drain of diameter D at the bottom of a pool of depth h as depicted above. Obviously, R > D/2 or the ball goes down the drain! Estimate the conditions under which the net force on the ball is zero for very small ratios of D/R (you can do the precise calculation for arbitrary D/R, but the math gets a little messy!). Assume that the pressure distribution in the drain is just atmospheric pressure, and that in the water is governed by the hydrostatic pressure distribution. If R is 1 ft and D is 6 inches, what is the corresponding depth?
- 5). Calculate the pressure at the center of the earth, assuming (for simplicity) a constant density of $5.67g/cm^3$ and radius of 3957miles. Give your final result in atmospheres. Hint: don't forget that gravity is a function of position!
