# Event-Triggered Sampling

## Event-Triggered Sampling:

[Arzen 99, Arzen 00]

- Sensor determines when to sample the system state.
- The “gap” between current state and past “sampled” state as a measure “novelty” in feedback information
- Sample the state when the “gap” exceeds a state-dependent threshold

## Benefits

- Reduced usage of computer and communication resources

# Periodic versus Event-triggered control

**Process Model:**  $dx = axdt + udt + dw$

Variance under Event Sampling =  $V_L$

Variance under Periodic Sampling =  $V_R$

**PID controller:**

$$G(s) = \frac{A}{(0.33s + 1)(0.17s + 1)}$$

**Event-trigger threshold:**

$$K(s) = 30 + \frac{40}{s} + \frac{2s\omega_d}{s + \omega_d}$$

$$|e(t)| = |x(t) - x(r_j)| \leq e_T = \text{threshold}$$

threshold chosen so peak error of both systems are equal

- Process Model:  $\dot{x}(t) = f(x(t), w(t)), \quad x(0) = x_0$
- Input-to-State Stability (ISS)

The system is ISS if there exists  $\mathcal{KL}$  function  $\beta$  and class  $\mathcal{K}$  function  $\gamma$  such that for any initial condition,  $x(0) = x_0$ , then the response under any input  $w \in \mathcal{L}_\infty$  for all  $t \geq 0$  satisfies

- ISS-Lyapunov Function

$C^1$  function  $V : \mathfrak{R}^n \rightarrow \mathfrak{R}$  is **ISS-Lyapunov** function if there exist class  $\mathcal{K}$  functions  $\underline{\alpha}$ ,  $\bar{\alpha}$ ,  $\gamma$ , and  $\beta$  such that

$$\begin{aligned} \underline{\alpha}(\|x\|) &\leq V(x) \leq \bar{\alpha}(\|x\|) \\ \dot{V} &\leq -\gamma(\|x\|) + \beta(\|w\|) \end{aligned}$$

If  $V$  is an ISS-Lyapunov function, then the system is ISS.

■ **Process Model:**  $G : \mathcal{L} \rightarrow \mathcal{L}$

■ **L2 Stability**

The system map  $G$  is  $\mathcal{L}_2$  stable if for all  $w \in \mathcal{L}_2$ ,  $\|Gw\|_{\mathcal{L}_2} \leq \gamma \|w\|_{\mathcal{L}_2} + \beta$

■ **Induced L2 Gain**

$$\|G\| = \inf \{ \gamma \in \mathbb{R} : \|Gw\|_{\mathcal{L}_2} \leq \gamma \|w\|_{\mathcal{L}_2} + \beta \}$$

# Hamilton Jacobi Inequality and $\mathcal{L}_2$ Gain

- Process Model:**

$$\dot{x}(t) = A(x(t)) + B_1(x(t))w(t) + B_2(x(t))u(t)$$

$$z(t) = \begin{bmatrix} x(t) & u(t) \end{bmatrix}^T$$

- Hamilton Jacobi Inequality:**

Assume there exists  $\gamma \geq 0$  and positive definite function  $V: \mathfrak{R}^n \rightarrow \mathfrak{R}$  such that

$$\frac{\partial V}{\partial x} A(x) + \frac{1}{2} \frac{\partial V}{\partial x} \left[ \frac{1}{\gamma^2} B_1(x) B_1^T(x) - B_2(x) B_2^T(x) \right] \frac{\partial V}{\partial x} + \frac{1}{2} x^T x \leq 0$$

- L2 Controller**

If the control  $u(t)$ , is selected so that  $u = -B_2^T(x) \frac{\partial V(x)}{\partial x}$

We can then show that

$$\dot{V} \leq -\frac{1}{2} (\|u\|_2^2 + \|x\|_2^2 - \gamma^2 \|w\|_2^2) = -\frac{1}{2} \|z\|_2^2 + \frac{1}{2\gamma^2} \|w\|_2^2$$

Integrating the above inequality yields

$$\|z\|_{\mathcal{L}_2} \leq \gamma \|w\|_{\mathcal{L}_2} + \sqrt{2\gamma V(x(0))}$$

which implies the L2 induced gain is less than  $\gamma$ .

References

- Consider the directional derivative of the function  $V$  that satisfies the earlier Hamilton-Jacobi Bellman inequality

$$\begin{aligned}
 \dot{V} &= \frac{\partial V}{\partial x} [A(x) + B_1(x)w + B_2(x)u] \\
 &\leq -\frac{1}{2} \frac{\partial V}{\partial x} \left( \frac{1}{\gamma^2} B_1 B_1^T - B_2 B_2^T \right) \frac{\partial V}{\partial x} - \frac{1}{2} \|x\|_2^2 + \frac{\partial V}{\partial x} B_2 u + \frac{\partial V}{\partial x} B_1 w && \text{HJI} \\
 &= \frac{1}{2} \left\| u + B_2^T \frac{\partial V}{\partial x} \right\|_2^2 - \frac{1}{2} \|u\|_2^2 - \frac{1}{2} \left\| \gamma w - \frac{1}{\gamma} B_1^T \frac{\partial V}{\partial x} \right\|_2^2 + \frac{\gamma^2}{2} \|w\|_2^2 - \frac{1}{2} \|x\|_2^2 && \text{Complete Square}
 \end{aligned}$$

If we let  $u = -B_2^T(x) \frac{\partial V(x)}{\partial x}$  then we can show

$$\dot{V} \leq -\frac{1}{2} (\|u\|_2^2 + \|x\|_2^2 - \gamma^2 \|w\|_2^2) = -\frac{1}{2} \|z\|_2^2 + \frac{1}{2\gamma^2} \|w\|_2^2$$

which is sufficient to ensure the  $\mathcal{L}_2$  induced gain is less than  $\gamma$

- Sequence of “release” times  $\{r_j\}_{j=0}^{\infty}$

- Sequence of sampled states

$$\hat{x}_j(t) = x(r_j) \text{ for all } t \in [r_j, r_{j+1})$$

- Gap between current state and sampled state

$$e_j(t) = \hat{x}_j(t) - x(t) \text{ for all } t \in [r_j, r_{j+1})$$

- Process Model** - discretely sampled state feedback

$$\dot{x}(t) = f(x(t), k(\hat{x}_j(t)), w(t)) = f(x(t), k(x(t) + e_j(t)), w(t))$$

for all  $t \in [r_j, r_{j+1})$  and all  $j = 0, \dots, \infty$

- ISS assumption** - under continuous sampling of state

“Continuously” sampled closed-loop system

$$\dot{x}(t) = f(x(t), k(x(t)), w(t))$$

is input-to-state stable with respect to the input  $w$ .

## ISS Event Trigger

- ISS assumption implies the existence of an **ISS-Lyapunov function**,  $V$   
There exist class  $\mathcal{K}$  functions  $\underline{\alpha}$ ,  $\bar{\alpha}$ ,  $\gamma$ ,  $\beta_1$ , and  $\beta_2$  such that

$$\underline{\alpha}(\|x\|) \leq V(x) \leq \bar{\alpha}(\|x\|)$$

$$\frac{\partial V}{\partial x} f(x, k(x+e), w) \leq -\gamma(\|x\|) + \beta_1(\|e\|) + \beta_2(\|w\|)$$

- ISS Event trigger:** [Tabuada 07]

If we can guarantee for all  $t \geq 0$  and all  $j = 0, \dots, \infty$  that

ISS event trigger

$$\beta_1(\|e_j(t)\|) \leq \sigma\gamma(\|x(t)\|)$$

for some  $\sigma \in [0, 1]$ , then we can ensure that

$$\dot{V} \leq -(1 - \sigma)\gamma(\|x(t)\|) + \beta_2(\|w\|)$$

which is sufficient to ensure the sampled system is ISS with respect to  $w$ .

# Event-triggering Example

■ **Process Model:**

$$\dot{x}(t) = f(x(t)) + u(t)$$

$$u(t) = -2f(\hat{x}_j(t))$$

■ **Event Triggerer:**

$$\beta_1(\|e_j\|) = e_j^2(t) \geq x^2(t) = \gamma(\|x(t)\|)$$

**sublinear**

$$f(x) = \text{sgn}(x)\sqrt{|x|}$$

**linear**

$$f(x) = x$$

**superlinear**

$$f(x) = x^3$$

■ **Three cases** in which system dynamic is sublinear, linear, or superlinear

- sublinear dynamics : exhibit Zeno sampling
- linear dynamics exhibit periodic sampling
- linear dynamics exhibit slow sampling around equilibrium point

# Lower Bound on Sampling Period

References

- **Lipschitz continuity of system**  $\|f(x, k(x+e))\| \leq L\|x\| + L\|e\|$
- **Lipschitz continuity of event trigger**

$$\beta_1(\|e_j\|) \geq \sigma\gamma(\|x(t)\|) \Rightarrow \gamma^{-1}(\sigma^{-1}\beta_1(\|e_j\|)) \leq \|x(t)\|$$

There exists positive constant  $P$  such that

$$\frac{1}{\sigma}\gamma^{-1}(\beta_1(\|e\|)) \leq P\|e\| \leq \|x\| \Rightarrow \frac{\|e\|}{\|x\|} \leq \frac{1}{P}$$

- **Bounds on rate of growth for the “event” quotient** [Tabuada 07]

$$\frac{d}{dt} \frac{\|e\|}{\|x\|} \leq \left(1 + \frac{\|e\|}{\|x\|}\right) \frac{L\|x\| + L\|e\|}{\|x\|} = L \left(1 + \frac{\|e\|}{\|x\|}\right)^2$$

This is a differential inequality that can be used to bound the evolution of the event quotient,  $\|e\|/\|x\|$

# Lower Bound on Sampling Period

## ■ Solution of the differential inequality

$$\frac{d}{dt} \frac{\|e\|}{\|x\|} \leq L \left(1 + \frac{\|e\|}{\|x\|}\right)^2 \quad \Rightarrow \quad \frac{\|e(t)\|}{\|x(t)\|} \leq \frac{tL}{1 - tL}$$

## ■ Lower bound on sampling period [Tabuada 07]

$$\frac{\|e(t)\|}{\|x(t)\|} \leq \frac{tL}{1 - tL} \leq \frac{1}{P} \quad \Rightarrow \quad r_{j+1} - r_j = T_j \geq \frac{1}{L + LP} > 0$$

## ■ Non-zeno Behavior

This bound is bounded away from zero so sampling interval never equals zero.

Earlier sublinear example exhibits Zeno behavior because  $f$  isn't Lipschitz

# $\mathcal{L}_2$ Event Triggers: process model

- **L2 event triggers** are chosen to preserve the induced L2 gain of a previously designed control system [Wang 09]
- **Process Model** - discretely sampled state feedback

$\dot{x}(t) = A(x) + B_1(x)w + B_2(x)u$ $z(t) = \begin{bmatrix} x(t) \\ u(t) \end{bmatrix}$ $u(t) = -B_2^T(\hat{x}_j) \frac{\partial V(\hat{x}_j)}{\partial x} = k(\hat{x}_j)$	<p>State sampled at release times <math>\{r_j\}_{j=0}^{\infty}</math></p> <p><math>\hat{x}_j(t) = x(r_j)</math> for all <math>t \in [r_j, r_{j+1})</math></p> <p>Sampling gap</p> <p><math>e_j(t) = \hat{x}_j(t) - x(t)</math></p>
--	--

- **L2 Controller**

$V$  is a storage function satisfying the HJI for some  $\gamma > 0$

$$\frac{\partial V(x)}{\partial x} A(x) - \frac{1}{2} \left\| B_2(x) \frac{\partial V(x)}{\partial x} \right\|_2^2 \leq -\frac{1}{2\gamma^2} \left\| B_1(x) \frac{\partial V(x)}{\partial x} \right\|_2^2 - \frac{1}{2} \|x\|_2^2$$

With this  $V$ , the continuously-sampled system's has a gain less than  $\gamma$ .

# $\mathcal{L}_2$ Event Trigger

- **Assumption:** Lipschitz continuity of L2 controller  $\|k(x) - k(\hat{x})\|_2 \leq L\|e\|_2$
- **Storage Function Rate of Change**

$$\dot{V} = \frac{\partial V(x)}{\partial x} (A(x) + B_1(x)w - B_2(x)k(\hat{x}))$$

$$(HJI) \leq -\frac{1}{2\gamma^2} \left\| B_1(x) \frac{\partial V(x)}{\partial x} \right\|_2^2 - \frac{1}{2} \|x\|_2^2 + \frac{\partial V(x)}{\partial x} B_1(x)w - k^T(x)k(\hat{x})$$

$$\text{complete square} \leq -\frac{1}{2} \|x\|_2^2 - \frac{1}{2} \left\| \gamma w - \frac{1}{\gamma} B_1^T(x) \frac{\partial V(x)}{\partial x} \right\|_2^2 + \frac{\gamma^2}{2} \|w\|_2^2 - k^T(x)k(\hat{x})$$

$$\text{Lipschitz} \leq -\frac{\beta^2}{2} \|x\|_2^2 + \frac{\gamma^2}{2} \|w\|_2^2 - \boxed{\frac{1-\beta^2}{2} \|x\|_2^2 - \frac{1}{2} \|k(\hat{x})\|_2^2 + \frac{1}{2} L^2 \|e\|_2^2}$$

- **Event Trigger** ensures that boxed term is always negative definite which implies the gain is less than  $\gamma/\beta$ 

$$L^2 \|e\|_2^2 \leq (1 - \beta^2) \|x\|_2^2 + \|k(\hat{x})\|_2^2$$

where  $(\mathbf{0} < \beta < 1)$

# $\mathcal{L}_2$ Event Trigger: example

- Process Model:

$$\dot{x}(t) = x^3 + u + w$$

$$u = -\alpha \hat{x}^3 - \hat{x}$$

$$w(t) = (e^{-2t} + \eta)\nu(t)$$

- Event Trigger:

$$L^2\|e\|_2^2 \geq (1 - \beta^2)\|x\|_2^2 + \|k(\hat{x})\|_2^2$$

$$\text{where } L = 1.e, \beta = 0.5, \gamma = 2, \text{ and } \alpha > \frac{2\gamma^2}{\gamma^2 - 1}$$

No Wideband noise:  $\eta=0$ Wideband noise:  $\eta=0.1$ 

- Example shows event-triggered systems sensitive to wideband noise

# Delays and Periods of $\mathcal{L}_2$ Event Triggers

## Sampling with delays

$r_j$  = release time of  $j$ th job  
(sample taken)

$f_j$  = finishing time of  $j$ th job  
(control applied)

$D_j$  = delay of  $j$ th job < Deadline

$T_j$  = Period of  $j$ th job

## LTI Process Model: for all $t \in [f_j, f_{j+1})$

Noise model:  $\|w(t)\| \leq W\|x(t)\|$

$$\dot{x}(t) = Ax + B_1 w + B_2 u$$

$$z(t) = \begin{bmatrix} x(t) \\ u(t) \end{bmatrix}$$

$$u(t) = -B_2^T P \hat{x}_j = k(\hat{x}_j)$$

## HJI becomes Riccati Inequality

$P$  is symmetric P.D. Matrix satisfying the Riccati inequality for some  $\gamma > 0$

$$A^T P + PA - P(B_2 B_2^T - \gamma^{-2} B_1 B_1^T)P + I \leq 0$$

## L2 Event Trigger

$$e_j^T(t) M e_j(t) \geq \delta x^T(r_j) N x(r_j)$$

[Wang 09]

where  $M = (1 - \beta^2)I + PB_2 B_2^T P$ ,  $N = \frac{1}{2}(1 - \beta^2)I + PB_2 B_2^T P$

## Lower Bound on Sampling Period: no delay

- Normalized gap function  $z_j(t) = \sqrt{M}e_j(t)$
- L2 Event Trigger:  $\|z_j(t)\| \geq \delta \sqrt{x^T(r_j)Nx(r_j)} = \delta\rho(x(r_j))$

- Sample Period Bound: no delay [Wang 09]

The normalized gap satisfies  $\frac{d}{dt}\|z_j(t)\|_2 \leq \alpha\|z_j(t)\|_2 + \mu_0(x(r_j))$

The solution to the differential inequality:  $\|z_j(t)\|_2 \leq \frac{\mu_0(x(r_j))}{\alpha} \left( e^{\alpha(t-r_j)} - 1 \right)$

which bounds the sampling period as  $\text{Period} = T_j \geq \frac{1}{\alpha} \ln \left( 1 + \alpha \frac{\delta\rho(x(r_j))}{\mu_0(x(r_j))} \right)$

# Bounds with Nonzero Delay

- With non-zero delay, the evolution of  $z_j(t)$  is governed by

$$\begin{aligned}\dot{x}(t) &= Ax(t) - B_2 B_2^T P x(r_{j-1}) + B_1 w(t) & \text{for } t \in [r_j, f_j] \\ \dot{x}(t) &= Ax(t) - B_2 B_2^T P x(r_j) + B_1 w(t) & \text{for } t \in [f_j, f_{j+1}]\end{aligned}$$

- Use differential inequalities to show that if **next release time** is

$$r_{j+1} = f_j + \frac{1}{\alpha} \ln \left( 1 + \alpha \frac{\delta \rho(x(r_j)) - \phi(x(r_j), x(r_{j-1}); D_j)}{\mu_0(x(r_j)) + \alpha \phi(x(r_j), x(r_{j-1}); D_j)} \right)$$

and if the delay satisfies the following **deadline**

$$D_j < \frac{1}{\alpha} \ln \left( 1 + \alpha \frac{(1 - \delta) \rho(x(r_j))}{\alpha \delta \rho(x(r_{j-1})) + \mu_0(x(r_{j-1}))} \right) = \text{Deadline}$$

then the sampled-data system is L2-stable [Wang 09]

## Agent's Dynamics

$$\dot{x}_i(t) = f_i(x_{D_i}(t), u_i(t), w_i(t))$$

$$\hat{x}_i(t) = x_i(r_j^i) \quad \text{for all } t \in [r_j^i, r_{j+1}^i)$$

$$u_i(t) = k_i(\hat{x}_{Z_i}(t)) \quad \text{for all } t > 0$$

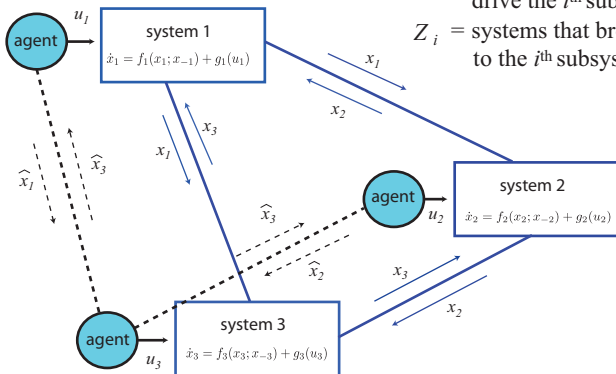

$x_i$  = local state

$\hat{x}_i$  = broadcast state

$r_j^i$  = broadcast time

$D_i$  = systems that physically  
drive the  $i^{\text{th}}$  subsystem

$Z_i$  = systems that broadcast  
to the  $i^{\text{th}}$  subsystem

Let  $e_i = \hat{x}_i - x_i$  denote the **gap** between agent  $i$ 's current state and its last broadcast state. Let  $V : \mathfrak{R}^{nN} \rightarrow \mathfrak{R}$  be a positive definite function so that there exist class  $\mathcal{K}$  functions  $\gamma_i$ ,  $\psi_i$ , and  $\beta_i$  such that

$$\dot{V} = \sum_{i=1}^N L_{f_i} V \leq \sum_{i=1}^N (-\gamma_i(\|x_i\|_2) + \psi_i(\|e_i\|_2) + \beta_i(\|w_i\|_2))$$

where

$$L_{f_i} V = \frac{\partial V}{\partial x_i} f_i(x_{D_i}, k(x_{Z_i} + e_{Z_i}), w_i)$$

This means that  $V$  is an ISS-Lyapunov function when the gap  $e_i = 0$ . In other words,  $k$  is an ISS controller for the "continuously" sampled networked system.

# ISS Event-Triggers in NCS

- Assume for  $\rho_i \in (0, 1)$ , the state and gap trajectories satisfy

$$-\rho_i \gamma_i (\|x_i(t)\|_2) + \psi_i (\|e_i(t)\|_2) \leq 0$$

for all  $t \in \mathfrak{R}$  and all  $i = 1, \dots, N$ . Then clearly

$$\sum_{i=1}^N L_{f_i} V \leq \sum_{i=1}^N (-(1 - \rho_i) \gamma_i (\|x_i\|_2) + \beta_i (\|w_i\|_2))$$

which implies the NCS is input-to-state stable.

- To enforce the previous "event-triggering" condition, we require the  $i$ th agent **broadcast** its state information to all of its neighbors in  $U_i$  whenever the triggering condition

$$\psi_i (\|e_i(t)\|_2) \leq \rho_i \gamma_i (\|x_i(t)\|_2)$$

is violated.

If broadcast is not “heard” by one agent in  $Z_i$ , then Broadcasting agent will not get ACKS from all of its neighbors and therefore will not transmit the PERM message

If the neighbors don't receive the PERM message, then they DROP the broadcast state information.

Using the prior event-trigger we can show that the gap satisfies

$$\|e_i^k(t)\| \leq \left( (1 + \hat{\delta}_i c_i)^{d_k^i + 1} - 1 \right) \|x_i(b_k^i)\| \leq \delta_i c_i \|x_i(b_k^i)\|$$

We obtain an upper bound on the admissible number of dropouts

$$d_k^i \leq \text{MANSD} = \left\lfloor \log_{1+\hat{\delta}_i c_i} (1 + \delta_i c_i) \right\rfloor - 1$$

Consider a “simple” canonical problem: [Rabi 06, Rabi 08]

- Finite Horizon,  $[0, M]$
- Discrete-time Scalar LTI System

$$x[k] = ax[k-1] + w[k]$$

$w[k]$  = zero mean white  
Gaussian noise with  
covariance  $q$

$x_0$  = initial state is normal  
random variable  $N(\mu_0, \pi_0)$

- Sensor transmits at time instant,  $r \in [0, M]$
- Least Square Estimate

$$\hat{x}[k] = E[x[k]|\mathcal{F}_k] = \begin{cases} \mu_0 a^k & k = 0, \dots, r-1 \\ x[r] a^{k-r} & k = r, \dots, M \end{cases}$$

# Transmission as Optimal Stopping

- The transmission time  $r$  is a random variable that is a **stopping time** of the random process  $\{x[k]\}$ . In particular this means

$$r = \min \{k : x[k] \notin S_k\}$$

where  $S_k$  is a set of **event sets**

- The problem is to determine these event sets such that the estimator's means square error is minimized

$$J(S_1, \dots, S_M) = E \left[ \sum_{k=1}^M (x[k] - \hat{x}[k])^2 \right] = E \left[ \sum_{k=1}^M \tilde{x}[k]^2 \right]$$

# Dynamic Programming

- This problem may be viewed as an optimal “control” problem in which the stopping events  $\{S_k\}$  are the “controls”. We can therefore use dynamic programming to solve the problem.
- Value Function,  $V(x,n)$ , is the optimal value obtained if the process starts at state  $x$  at time  $n < M$ .
- **Bellman’s Principle of Optimality** says that if  $\{u^*[n]\}_{n=k}^M$  is an optimal control generating state trajectory  $\{x^*[n]\}_{n=k}^M$  from initial state  $(x^*[k], k)$  to  $M$ , then  $\{u^*[n]\}_{n=k+1}^M$  is the optimal control from initial state  $(x^*[k+1], k+1)$  to  $M$ .

$$\begin{aligned}
 V^1(y, k) &= \min_{S_k, \dots, S_M} E_{r, \tilde{X}_k^M} \left[ \sum_{j=k}^M \tilde{x}^2[j] \mid \tilde{x}^-[k] = y, k \leq r \leq M \right] \\
 &= \text{minimum cost from } k \text{ to } M \text{ when transmission occurs } \mathbf{after} \ k - 1 \text{ and a priori est. error is } y. \\
 V^0(y, k) &= \min_{S_k, \dots, S_M} E_{r, \tilde{X}_k^M} \left[ \sum_{j=k}^M \tilde{x}^2[j] \mid \tilde{x}^-[k] = y, k > r \right] \\
 &= \text{minimum cost from } k \text{ to } M \text{ when transmission occurs } \mathbf{before} \ k \text{ and a priori estimation error is } y
 \end{aligned}$$

# Optimal Event-Triggered Transmission Thresholds

- The minimum cost is achieved by  $J^* = E [V^1(\tilde{x}_0, 0)]$ . We can use Bellman's principle to compute this in a backward recursion.

$$V^1(y, k) = \min \{F_k(y), G_k(q)\}$$

where

$$\begin{aligned} G_k(q) &= E_{\tilde{x}[k+1]} [V^0(k+1, \tilde{x}^-[k+1]) | \tilde{x}[k] = 0] \\ &= \text{Cost if transmission occurs at time } k \end{aligned}$$

$$\begin{aligned} F_k(y) &= y^2 + E_{\tilde{x}[k+1]} [V^1(k+1, \tilde{x}^-[k+1]) | \tilde{x}[k] = y] \\ &= y^2 + G_{k+1}(q) - \int_{S_{k+1}} [G_{k+1}(q) - F_{r+1}(\tilde{x}[r+1])] dP_{\tilde{x}[k+1]} \\ &= \text{Cost if transmission occurs after time } k \text{ given error is } y \end{aligned}$$

- The optimal control (stopping event) is easily obtained from the choice implied by the backward recursion

$$u^*[k] = \begin{cases} 0 & \text{don't sample} & F_k(\tilde{x}[k]) < G_k(q) \\ 1 & \text{sample} & F_k(\tilde{x}[k]) \geq G_k(q) \end{cases}$$

This is an event-triggered threshold logic.

# Suboptimal Transmission Thresholds

- The threshold function  $F_k$  can be computed numerically off-line.
- We can also adopt a sub-optimal approach by noting that

$$\begin{aligned} F_k(y) &= y^2 + G_{k+1}(q) - \int_{S_{k+1}} [G_{k+1}(q) - F_{k+1}(\tilde{x}[k+1])] dP_{\tilde{x}[k+1]} \\ &\leq y^2 + G_{k+1}(q) \end{aligned}$$

- which leads to a stopping event that is only dependent on the process noise covariance  $q$ .

$$S_k^+ = \left[ -\sqrt{\frac{1 - a^{2(M-k)}}{1 - a^2}} q, \sqrt{\frac{1 - a^{2(M-k)}}{1 - a^2}} q \right]$$

which is an inverse quadratic threshold that goes to zero as  $k$  goes to  $M$ .

# Simulation Results

- Simulation of optimal, suboptimal, and periodically sampled schemes where  $M = 10$ ,  $q = 1$ , and  $w_k \in N(0, 1)$ .

$a = 0$ (stable)	periodic	suboptimal	optimal
$J$ (cost)	9.98	8.50	7.68
$r$ (sampling time)	5	3.13	7.1

$a = 1$ (unstable)	periodic	suboptimal	optimal
$J$ (cost)	30.15	21.70	21.68
$r$ (sampling time)	5	7.01	7.56

- Simulation results show that
  - $J^* < J^+ < J_p$ , so that optimal policy is indeed optimal
  - $J^+ \approx J^*$  when process is unstable (forgets initial condition quickly)
  - optimal policy always delays sampling longer than periodic policy - but this is not necessarily true for suboptimal sampling policy.

Research Issues

References

- Recast as a dual min-max problem  
minimize:  $\max_{x \geq 0} \left( \sum_{i=1}^N U_i(x_i) - p^T (Ax - c) \right)$   
subject to:  $p \geq 0$   
where the vector  $p$  is a set of **shadow prices** that each link charges its users.
- Solve this problem in an “alternating” manner where
  - each “link” selects a price based on observed user rates
  - each user selects its rate based on the transmitted prices
- An algorithm known as “dual-decomposition” allows us to implement this “alternating” recursion in a highly distributed manner [Low 99]

- **Dual-decomposition** [Low 99] is a “distributed” algorithm commonly used to solve the dual form of the NUM problem

$$x_i[k+1] = \arg \max_{x \geq 0} \left( U_i(x_i[k]) - x_i[k] \sum_{j \in L_i} p_j[k] \right) = \left( \sum_{j \in L_i} p_j[k] \right)^{-1}$$

$$p_j[k+1] = \max \left\{ 0, p_j[k] + \gamma \left( \sum_{i \in S_j} x_i[k] - c_j \right) \right\}$$

where  $U_i(x_i) = \log(x_i)$  where is the user’s utility function

- $\gamma$  is a step size chosen to ensure convergence [Low 99]

$$0 < \gamma < \frac{-2 \max_{(i, x_i)} \nabla^2 U_i(x_i)}{\bar{L} \bar{S}}$$

where  $\bar{L}$  is maximum number of links that any route uses and  $\bar{S}$  is the maximum number of users on any link.

- $\bar{L}$  and  $\bar{S}$  are measures of network complexity. So the number of messages passed by dual-decomposition increases with longer routes and neighborhoods.

# Augmented Lagrangian Algorithm

## Event Triggered Feedback

M.D. Lemmon

Embedded Control

Networked Control System

Estimation

Optimization

Research Issues

References

- Event-triggered NUM algorithm is best implemented using an “interior-point” algorithm based on an Augmented Lagrangian.

- Augmented Lagrangian** of the NUM problem

$$L(x; \lambda, w) = - \sum_{i=1}^N U_i(x_i) + \sum_{j=1}^M \psi_j(x; \lambda, w)$$

where  $\psi_j(x; \lambda, w)$  is a constraint penalty

- Primal Augmented-Lagrangian** algorithm

- Sequence  $\{\lambda_j[k]\}$  of Lagrange Multipliers

$$\lambda_j[k+1] = \lambda_j[k] + \frac{1}{w_j} (a_j^T x[k] - c_j)$$

- Compute approximate minimizer  $x^*[k]$

$$x^*[k+1] = \arg \max L(x; \lambda[k], w)$$

# Distributed Augmented Lagrangian Algorithm - continuous access

## Event Triggered Feedback

M.D. Lemmon

Embedded Control

Networked Control System

Estimation

Optimization

Research Issues

References

- Users compute the approximate minimizer using a gradient following algorithm.

$$x_i(t) = \int_0^t \left( \frac{\partial U_i(x_i(\tau))}{\partial x_i} - \sum_{j=1}^M \mu_j(\tau) A_{ji} \right) d\tau +$$

where the links update the variable

$$\mu_j(t) = \left( \lambda_j + \frac{1}{w_j} \left( \sum_{i=1}^N A_{ij} x_i(t) - c_j \right) \right) +$$

- Note that these two equations define a feedback loop between users and links in the players have “continuous” access to each others’ states.
- In practice, link updates are carried over packet switched network, so that users only have “discrete” access to link states.

link states transmitted over communication network

user rates observed by each link router

# Broadcasting Link States

References

- With discrete access to "link" states, let  $\{T_j^L[\ell]\}_{\ell=0}^{\infty}$  be the time instants when link  $j$  transmits its link state to its users. The link state received by the users is

$$\hat{\mu}_j(t) = \mu_j(T_j^L[\ell])$$

- With this sampled link state, the user's gradient algorithm becomes

$$x_i(t) = \int_0^t \left( \frac{\partial U_i(x_i(\tau))}{\partial x_i} - \sum_{j=1}^M \hat{\mu}_j(\tau) A_{ji} \right)^+ d\tau$$

- If we treat  $L(x; \lambda, w)$  as a candidate Lyapunov function then we need to examine  $\dot{L}(x; \lambda, w)$

prices transmitted at discrete instants over comm. network

user rates observed by  
each link router

# Convergence Analysis

- Let  $z_i$  be the  $i$ th user state's rate of change

$$z_i(t) = \dot{x}_i(t) = \left( \frac{\partial U_i(x_i(t))}{\partial x_i} - \sum_{j=1}^M \hat{\mu}_j(t) A_{ji} \right)^+$$

- Let  $L(x; \lambda, w)$  be a candidate Lyapunov function

$$\begin{aligned} \dot{L}(x; \lambda, w) &= \sum_{i=1}^N \frac{\partial L}{\partial x_i} \frac{dx_i}{dt} = - \sum_{i=1}^N z_i \left( \frac{\partial U_i(x_i(t))}{\partial x_i} - \sum_{j=1}^M \mu_j A_{ji} \right) \\ &\leq - \sum_{i=1}^N \left[ \frac{1}{2} z_i^2 - \frac{1}{2} \left( \sum_{j=1}^M (\mu_j - \hat{\mu}_j) A_{ji} \right)^2 \right] \\ &\leq - \frac{1}{2} \sum_{i=1}^N z_i^2 + \frac{1}{2} \sum_{j=1}^M \bar{L} \bar{S} (\mu_j - \hat{\mu}_j)^2 \end{aligned}$$

- We can't use this to directly set up an event trigger for the link.

# Convergence Analysis and Event Triggers

- We need "local" conditions that can ensure  $\dot{L}(x; \lambda, w)$  is negative definite. So introduce a sequence  $\{T_i^S[\ell]\}_{\ell=0}^{\infty}$  of time instants when the  $i$ th user transmits its modified state,  $z_i$ , to its links. The transmitted user state is

$$\hat{z}_i(t) = z_i(T_i^S[\ell])$$

- We can now rewrite our bound on  $\dot{L}$  as

$$\dot{L}(x; \lambda, w) \leq -\frac{1}{2} \sum_{i=1}^N [z_i^2 - \rho \hat{z}_i^2] - \frac{1}{2} \sum_{j=1}^M \left[ \rho \sum_{i \in S_j} \frac{1}{L} \hat{z}_i^2 - \bar{L} \bar{S} (\mu_j - \hat{\mu}_j)^2 \right]$$

where  $\rho \in (0, 1)$ .
